Abstract

When you see a patient with solid mesenteric tumors, malignant lymphoma should be considered as an important differential diagnosis. It is essential to include abdominal CT and ^{18}F -FDG PET/CT examinations in these patients for early diagnosis of malignant lymphoma, giving extra weight on patients' complaints.

KEYWORDS

follicular lymphoma and PET-CT, mesenteric tumors

1 | CASE

A 72-year-old man was referred to our hospital for evaluation of a huge mass on CT (Figure 1A, arrows). He presented to the previous hospital with awareness of non-tender abdominal mass. He was otherwise asymptomatic. ^{18}F -FDG PET/CT revealed a bulky mesenteric mass (13 cm diameter) with a maximum standardized uptake value of 13.26 (Figure 1B). He underwent laparotomy for excisional biopsy, which were compatible with follicular lymphoma. He was treated with bendamustine plus rituximab. He has been followed up on outpatient basis and has had no recurrent disease to date.

Primary mesenteric tumors are very rare, with incidence of <1 in 200 000, and follicular lymphoma is the most common histological type.¹ There are various imaging patterns of mesenteric lymphoma at CT; including rounded, enhancing, or homogenous masses. Although the sandwich sign, bulky lymphadenopathy in the mesentery encasing vessels and the bowel, is known to be suggestive of malignant tumors,² its diagnostic performance has been unknown. Because mesenteric lymphoma may be indolent, a focus on patient complaints, such as awareness of mass as this case, is essential for early diagnosis. Among solid mesenteric tumors, malignant lymphoma should be considered a priority.

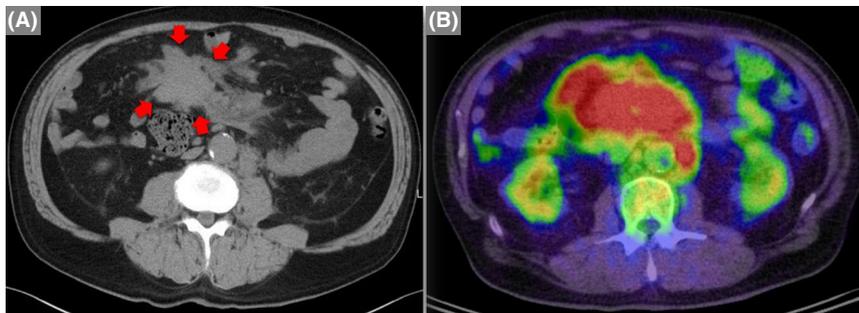

FIGURE 1 A, Noncontrast CT demonstrated a huge intraperitoneal mass (13 cm diameter) (arrows). B, Fluorine-18-fluorodeoxyglucose positron emission tomography-CT showed a bulky mass with a maximum standardized uptake value of 13.26
